

How to wire a parallel distribution box

Article Overview

Parallel distribution boxes should be wired by connecting each circuit individually from the main switch using proper connectors, avoiding jumpers, and ensuring all wires are correctly insulated and secured.

Understanding Parallel Wiring

Parallel wiring in a distribution box involves connecting multiple circuits so that each branch receives power independently from the main supply. This is often done using busbars or parallel connectors, not by jumpering wires from one breaker to another, which is unsafe and prohibited by standards. Each wire should carry only the current for its own circuit to prevent overloads and ensure proper protection.

Step-by-Step Wiring Process

- **Safety First:** Turn off the main power supply before starting any wiring to prevent electrical shock.
- **Prepare Wires:** Strip the insulation from the ends of each wire (typically 10mm for load and grid wires) and use appropriate terminals for crimping.
- **Connect Main Supply:** Attach the incoming live (L), neutral (N), and ground (G) wires to the main terminals of the distribution box. Ensure correct polarity and secure connections.
- **Branch Circuit Connections:**
 - Use individual wires from the main switch to each circuit breaker.
 - Avoid using jumper wires between breakers, as this can cause the first wire to carry the sum of all downstream currents, leading to overloads that may not trip the breaker
