

Reasons why the inner sheath of optical cables is difficult to peel

Overview

High-quality cable sheaths resist these damages through excellent abrasion resistance, impact and compressive strength, and reasonable tensile strength and flexibility. In cable design, the inner sheath and outer sheath are both protective layers, but they are not the same. The inner sheath is usually located between the cable core and the outer protective layer, while the outer sheath is the external layer that protects the whole cable from moisture, abrasion, UV. If the fiber cracks in a cable assembly, the connection is weakened or lost. Your cable assembly house could face repairing or replacing connectors in the field, which could be exceedingly costly for your company. To discuss the way forward, we need to understand them one by one. Smaller core = longer distance, less dispersion. However, they are composed of many components, each constructed from advanced materials to guarantee the quick and reliable transmission of data.
